

METEORS

In this list of the year's meteor showers for 2017, "(14)" for example means the expected time of the peak, in Universal Time. The prediction can be uncertain. Some showers have sharp peaks of only a few hours, some are very broad and indefinite.

"Jan 15-25" (for example) is the span of time over which at least a few meteors of the shower may be seen.

Boldface denotes some of the better-known showers.

The phase of the Moon near to the time of a shower is given because moonlight is (after clouds and light-pollution) the chief limiter of meteors' visibility. If a Full Moon is in the sky, only the few brightest meteors may be seen.

"ZHR" is zenithal hourly rate, the theoretical number of meteors per hour that one observers might see at the peak, in the zenith, in perfect conditions. So the actual rates seen are usually less.

The names of the showers are derived from the constellations in which are their radiants. (Quadrans Muralis was a constellation that is no longer used.) Meteors of, for instance, the Leonid shower may be seen in any part of the sky, but show themselves to be Leonids if their paths, projected backward, intersect in Leo
